and its movement is controlled by a cam plate which is mounted upon the ball valve and which is rotated in response to turning the control lever of a conventional gate valve, the cam plate being formed as an integral part of the ball valve. Plug valve elements are widely used in many industries, and the use of ball valves is expanding rapidly in commercial and industrial applications, particularly in underground pipe work and in handling corrosive materials. With conventional ball valves of the prior art, the valve is opened and closed by rotating the stem or operating lever that is mounted for rotation in the ball head so that rotation of the stem rotates the ball member to open or close the flow through the valve. A ball valve of the type described above is disclosed in U.S. Pat. No. 3,589,952 in which the ball is rotated by the stem through an angle of 90.degree.. Movement of the stem is accomplished through the rotation of a stem ring rotatably mounted within the ball head and rotatable by means of a screw thread connection to the ball member. A valve seat plate is mounted in the ball head by a plurality of screws and is rotatable in the ball head with the ball member to provide a closeable flow through the valve. A valve plate is mounted in the valve body and the valve is opened and closed by rotating the stem to rotate the ball member. A ball valve of the type described above has several shortcomings. The use of screws to mount the valve seat plate in the ball head creates a weak structure and it is necessary to utilize relatively large diameter screws to obtain a secure and strong mounting of the valve seat plate. The use of screws to mount the valve seat plate also creates a weak structure at the interface between the valve seat plate and the ball member. The structural requirements of the ball head also necessitates that the 5b5f913d15
